TITLE:

The Operation of Valves With Rubber Packings (Rabota klapanov

s rezinovym uplotneniyem)

PERIODICAL:

Priborostroyeniye, 1958; Hr 10; pp 7-11 (USSR)

ABSTRACT:

Air-crew masks, oxygen masks and pneumatic regulators must have valves that close perfectly. The conditions for a perfect operation of the valve packings are derived theoretically and experimentally or are investigated, respectively.

This investigation covers the two valve systems:

a) Valve with direct action, gas pressure "under the valve".

b) Nonreturn valve, gas pressure "on the valve".

Especially the sealing forces are derived.

The correct operation of the valves is checked experimentally. For the production of the valve seat an especially useful shape is given. The main attention has to be paid to the smoothness of the seat face (vvv 9 or vvvv 10). The relative pressure on the packing material which has to be applied to the unit of length of the valve seat to secure an absolute tightness is measured. (It is expressed by  $\alpha$  in kg/cm). The

The Operation of Valves With Rubber Packings

SOV/119-58-10-3/19

a-values are determined for the following diameters of the valve seats: 6.2; 4.2; 2.9 and 2.2 mm, with rubber of the type V-14 ~ 2 mm thick ~ (hardness according to Shoru = 80 - 82), and of the type N-14, group : G - 3.4 mm thick (hardness according to Shoru = 68 - 74) being used.

The dependence measured between the sealing force and the gas pressure to be controlled takes a linear course.

Also the increase of the sealing force was experimentally determined in the case that the sealing valve is tilted by 1 degree to the valve seat. From the graph obtained may be concluded that the increase of the sealing force is linearly proportional to the diameter of the valve seat and that it practically does not depend on the thickness and the hardness of the rubber. There are 7 figures and 7 references, 7 of which are Soviet.

"Flow past wines with deflected adlarens at one ro nic spe ds."

和表示。1. **相似和我们的对话的**和我们的有效的。

The flow past allerons of a supersonic gas flow is considered in presence of a wing located under a zero incidence angle. It is assumed that the thickness of the wing and of the allerons and the angles of deflection of the allerons are sufficiently small. Seven fundamental cases are considered depending on the shape of the wing and the allerons and on the Mach number of the incident flow. For each case formulae are given for calculating the pressure distribution (para. 2). In para. 3 the formulae are derived for determining the aerodynamic characteristics of the alleron for the first case. The results obtained in this paper can also be utilized for the aerodynamic calculation of other control or; ans of aircraft. (First published in 1949).

THE PROPERTY OF THE PROPERTY O

TITLE: Dynamics of the geomagnetic trap and the origin of radiation belts

SOURCE: Kosmicheskiye issledovaniya, v. 3, no. 2, 1965, 336-340

TOPIC TAGS: magnetosphere, solar wind, geomagnetic field, magnetic storm, force line, proton belt, electron belt

ABSTRACT: The boundary of the magnetosphere created by the interaction between the solar wind and the geomagnetic field reaches a distance of 10 terrestrial radii on the day side of the earth. Electric currents on the boundary increase the magnetic field there. On the night side the magnetosphere is very extended. A particle may pass through the boundary of the magnetosphere because of a radial drift of the particle is an asymmetric magnetic field. The physical processes are studied in a magnetic field from parallels #70°. The regions permitting and prohibiting particle motion are determined,

ACCESSION NR: AP5009654 following Stormer's theory. Boundary currents diminish the magnetic field at neutral points. This effect shows up in the beginning of a magnetic storm. The combination of the current field and the dipole serves to straighten the force lines in the magnetosphere and stretch them towards the solar wind. The proton belt is nearer the earth than the electron belt. Orig. art, has: 3 figures and 2 formulae.

ABSTRACT: The alloys were made in a Tammann furnace in a current of

Ar with electrolytic Fe and an As alloying compound, the latter being produced by briquetting of 30% powdered As and 70% electrolytic Fe. The liquidus line was determined by thermal analysis in a Kurnakov pyrometer. Homogenizing of the alloys was performed at 800-1200°C. The investigation was by the study of the quenched microstructure. In alloys with Fe', As forms an enclosed field. The concentrations of solid (x and solutions in equilibrium at 1150°, in which the solop is of maximum extent, were found to be 1.75 and 4.2% respectively. The eutectic transformation temperature was found to be 840°. The maximum solubility

of As in QFe, determined by X-ray analysis of the structure is Card 1/1 12.4% and 840° and 5% at room temperature. L.V.

pp 58-64

ABSTRACT: The alloys were smelted of metallic As (96%), Armco Fe,

electrolytic Fe, and an alloy containing ~5% C in a Tammann furnace. Homogenization was done at 900-1200°C during 6-8 hr, which fully eliminated dendritic liquation of As. Investigation was conducted by the methods of differential dilatometric analysis and by microstructural methods of measuring of resistivity during heating. Four cross sections were constructed for constant As contents: 0.8, 1.4, 2.8, and 4.5%. As was above points A<sub>1</sub> and A<sub>3</sub>. At 1.75% As the  $\alpha+\beta$  and  $\delta+\beta$ regions unite. At 2.4% As the  $\propto$  and  $\delta$  regions unite. The

temperature of the solidus drops sharply with an increase in As content (by 220-3200 depending on C content.) The temperature

of the eutectic transformation L  $\longrightarrow$   $\uparrow$  + Fe<sub>3</sub>C with 4.5% As

Effect of Phosphorus and Arsenic on the Lattice Parameter and Hardness of & -Iron

45 and 10 hrs at 400, 500, 650 and 810°C)
From these data solid solubility of P and As in X-iron at various temperatures was determined. The solid solubility curve of phosphorus in X-iron is shown on Fig.3, that showing solubility of arsenic in X-iron is reproduced in another article (Ref.12). Both phosphorus and arsenic were found to increase hardness of X-iron. The micro and macro-hardness curves (graphs a and b) for the Fe.P and Fe.As Alloys are shown on Fig.4 and 5 respectively. The difference between the values of Ficro and macro-hardness are attributed to the fact that the former was determined

The phase diagram iron - hafnium

analysis was described previously (V. N. Sve\_nnikov & al., Ref. 12; Mashinostroyeniye, No. 5, 76 (1960)). Tungsten-iridium thermocouples and BP5/20 (VR 5/20) (W + 5% Re  $\longrightarrow$  W + 20% Re) were used. The dilatometer is also described in Ref. 12. The phase components of the alloys were determined by X-ray structural analysis. A filtered cobalt Kd-radiation in a cylindrical camera was used. The Curie point of the alloys was determined\_with the anisometer by Akulov [Abstracter's note: Anisometer not stated] (methods: V. G. Permyakov & al., Zav. lab., 21, No.6,695 1955)). The authors established that in alloys with less than 45% Hf four transformations take place in the solid state: Two magnetic ones in &-iron and in the intermetallide, a third which is linked with the transformation of A-iron into Y-iron, and a fourth which corresponds to the transformation of y-iron into d-iron. The heat of transformation for was determined dilatometrically at a heating rate of up to 0.5 deg/min. The  $\not\sim$   $\rightarrow$   $\nearrow$  transformation took place in the initial iron (Ccontent up to 0.01%) at a heating rate of 0.2-0.3 deg/min between 894 and 905°C. The heating and cooling dilatograms do not permit the distinction between the transformation  $\alpha+\epsilon \rightarrow \gamma + \epsilon$  and  $\alpha \rightarrow \gamma$ . The greatest solubility of Hf in  $\alpha$ -Fe (peritectic point) amounts to 0.2%. It was Card 2/6

APPROVED FOR RELEASE: 08/23/2000 CIA-RDP86-00513R001550220020-4"

25858 s/020/61/139/004/018/025 b103/b206

The phase diagram iron - hafnium

RESIDENCE DESCRIPTION OF THE CONTRACT OF THE C

determined on the basis of the intersection point of the peritectic horizontal with the extrapolated curve of the  $\alpha$  transformation. Characteristic features were a) the temperature increase of the transformation  $\alpha + \beta = 1/2 + \xi$  with increasing Hf content in alloys, and b) the spreading of the transformation over a considerable temperature interval.

For this reason, the above temperature which amounts to  $935^{+}5^{\circ}C$ , was determined from the dilatogram of the two-phase alloy  $(\alpha+\xi)$ , whose composition lies closest to the peritectic point. The transformation f(x) = f(x) takes place on the basis of a eutectic reaction at f(x) = f(x). The transformation of the peritection at f(x) = f(x) takes place on the basis of a eutectic reaction at f(x) = f(x).

eutectic alloy contains 2.8% Hf. At  $1330^{\circ}$ C, the maximum Hf solubility in eutectic alloy contains 2.8% Hf. At  $1330^{\circ}$ C, the maximum Hf solubility in V-Fe is 1.6%. In alloys with 70-99% Hf, two transformations take place in the solid state: 1) magnetic transformation of the intermetallide; the coefficient of thermal expansion is strongly changed here; 2) eutectic

transformation at 1235 $^{\pm}$ 10°C according to the reaction:  $\ell$ + $\alpha_{\rm Hf} \longleftrightarrow \beta_{\rm Hf} + \ell$ .

2) is accompanied by a noticeable thermal effect and a considerable volume increase (during heating). From this, the authors conclude that the

Card 3/6

25858 S/020/61/139/004/018/025 B103/B206

The phase diagram iron - hafnium

solubility of Fe in Hf is low (certainly below 1%). The fusibility diagram was drawn up only on the basis of a differential thermal analysis. The authors established two eutectic transformations in the system Fe - Hf: A)  $L \rightleftharpoons \beta_{Hf} + \mathcal{E}$  at  $1300^{\pm}10^{\circ}C$  and B)  $L \rightleftharpoons \beta + \mathcal{E}$  at  $1350^{\pm}10^{\circ}C$ . The Hf content in the eutectic alloys is 85 and 21.5%, respectively. The crystal lattice of the alloys containing the intermetallide Fe2HF (E-phase) was determined by X-ray structural analysis as being hexagonal and of the MgZn, type. parameters of this lattice were not the same in alloys of various compositions. From this, the authors conclude that a considerable range of homogeneity of the &-phase exists in some alloys. The boundaries of the mono-phase range were found at  $1200^{\circ}\text{C}$  by direct determination of the hafnium content in the E-phase. I. D. Marchukova (Institut metallurgii AN SSSR - Institute of Metallurgy, AS USSR) made the cnemical analysis of this phase by X-ray structural analysis with the PcAw-2 (RSASh-2)apparatus. In the  $\mathcal{E}$ -phase of alloy no. 18, 50% Hf were formed, and in no. 21 64%. Since Fe, Hf is ferromagnetic, the Curie point of the &-phase was determined Card 4/6

"但他的,也在我们们<mark>是是我们的是我们的</mark>的数据的对象的是是是我们的是我们的是我们的一点,我们们还是

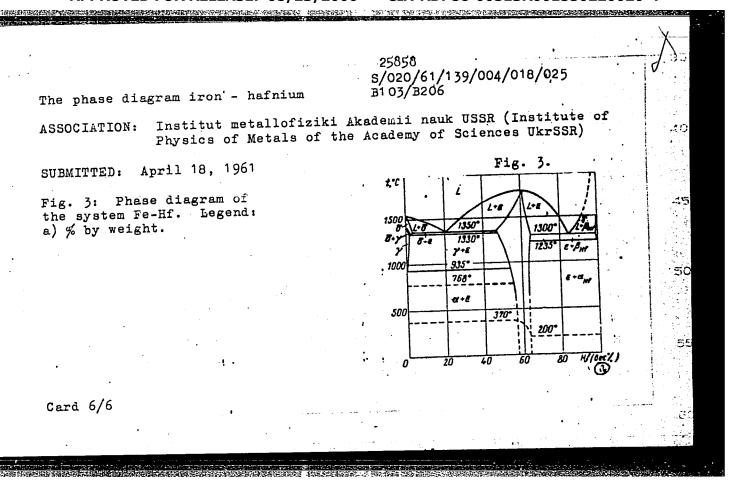

25858 \$/020/61/139/004/018/025 B103/B206

The phase diagram iron - hafnium

in several alloys, i. e., for various compositions of the &-phase. this way, it was proved that the Curie point drops from 405 to 145°C with an increase of the Hf content in the intermetallide from 50 to 64%. The composition of the ?-phase in the alloys was changed owing to long annealing (over 100 hr). The Curie point dropped in alloy .no. 18 from 405 to  $377^{\circ}$ C, and in no. 21 it increased from 145 to  $170^{\circ}$ C. boundaries of the mono-phase range of the intermetallide were determined in this way. The hardness of the intermetallide (determined with the Vickers device) is 650 kg/mm<sup>2</sup>, and its melting point is  $1810\pm20^{\circ}$ C (for stoichiometric Fe, Hf), which is much higher than that mentioned by R. P. Elliot, W. Rostocker (Trans. Am. Soc. Metals, 50, 617 (1958)). authors thank I. B. Borovskiy for making the spectral analysis in his laboratory. There are 3 figures, 1 table, and 13 references: 2 Sovietbloc and 11 non-Soviet-bloc. The two important references to Englishlanguage publications read as follows: P. Duwes (Ref. 5: J. Appl. Phys., 22, No. 9, 1174 (1951); H. K. Adenstedt (Ref. 2: Trans. Am. Soc. Metals, The third one see in the body of the abstract. <u>44</u>, 949 (1952). Card 5/6

Svechnikov, V.N. and Shurin, A.K.

Constitution diagram of the Fe-C-Hf system AUTHORS:

Intsytut metalo-Akademiya nauk Ukrayins'loyi RSR. TITLE:

fyzyky. Sbornik nauchnykh rabot. no. 16. Kiyev, 1962. Voprosy fiziki metallov i metallovedeniya.

SOURCE:

In continuation of their earlier work (DAN SSSR, 139, ho. 4, 895-898, 1961) on the Fe-Hf system, the authors studied the Fe corner of the Fe-Hf-C constitution diagram, embracing alloys with up to 1.7% C and 20% Hf. High-purity materials were used for the preparation of experimental alloys whose constitution was determined with the aid of thermal and X-ray diffraction analyses, dilatometric measurements and metallographic examination of specimens quenched from various temperatures. Some of the results are reproduced in Fig. 1, showing vertical sections through the Fe-C-Hf system at 0.9, 4, 10 and 20% Hf. The vertical sections at 0.25, 0.55, 1.15. and 1.65% C are shown in Fig. 2. It has been at 0.25, 0.55, 1.15. and 1.65% C are shown in Fig. 2. established that the carbide formed in the Fe-Hf-C alloys has Card 1/3

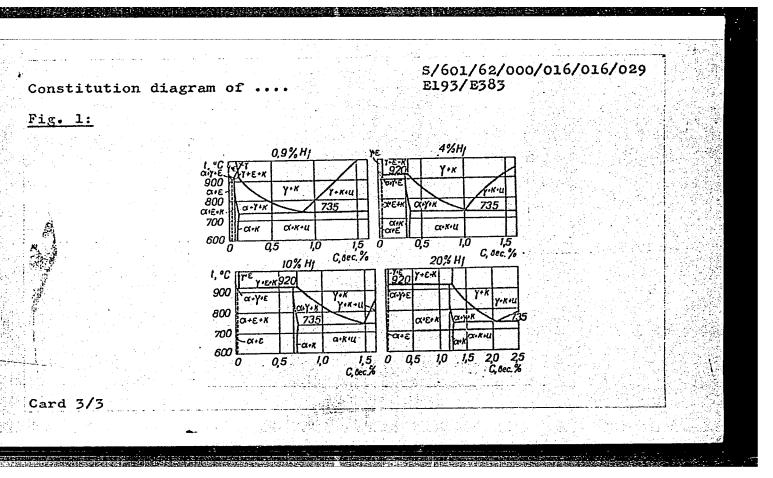

s/601/62/000/016/016/029 E192/E382

Constitution diagram of ....

formula "HfC"; the regular shape of the HfC crystals indicates that they crystallize out of the melt. In general, Hf sharply decreases the width of the single-phase \gamma-region, considerably increases the C content in the eutectoid and reduces the proportion of pearlite; this constituent is not oberved at C concentrations of less than 0.7% in alloys containing 10% Hf. Practically all the C combines with Hf at low C concentrations and cementite is formed only then the C content is higher than that required to combine all the Hf present. There are two four-phase nonvariant peritectoid equilibria in the concentration range studied:

1)  $(\alpha + K \rightleftharpoons \Box + \gamma)$  is observed at 735 °C, the four participating phases being  $\alpha - \alpha + \gamma$  is observed (Hfc),  $\Box - cementite$  (Fe<sub>3</sub>°C) and  $\gamma - \gamma - r$ °C; the other  $(\alpha + K \rightleftharpoons \gamma + \varepsilon)$  is observed at 920 °C, and  $\gamma - r$ °C; the intermetallic compound Fa Hf E denoting the intermetallic compound Fe2Hf. There are 3 figures, January 26, 1962 SUBMITTED:

Equipment for the physico-chemical investigations on TITLE:

high-melting chemically active metals

Akademiya nauk Ukrayins'koyi RSR. Instytut metalfyzyky. SOURCE:

Sbornik nauchnykh rabot. no.16. Kiev, 1962. Voprosy

fiziki metallov i metallovedeniya. 220-230

The following equipment has been developed over several TEXT: years in the Otdel metallovedeniya (Department of Science of Metals) of Institut metallofiziki AN UkrSSR (Institute of Physics of Metals AS UkrSSR) for studying alloys such as chromium-niobium-1) Arc furnace, including casting facilities, in which evacuation to  $10^{-2}$  mm is followed by admission of argon to a pressure of 0.2 atm. [Abstracter's note: 10-2 mm is a very poor vacuum and the equipment would not work as described. is then purified in the furnace by a molten titanium getter. A rotary arrangement enables a clean section of the inspection window to be moved into position without breaking the vacuum. 2) Argon purification plant in which air and moisture are removed Card 1/2

Equipment for the physico-

S/601/62/000/016/029/029 E111/E451

by calcium chips at 700 to 750°C, through which a 250 litre batch of gas circulates by convection. 3) Installations for annealing specimens in vacuum or argon at temperatures up to 1000°C and up to 2500°C respectively. 4) An installation for differential thermal analysis in an inert medium at temperatures up to 2000°C with novel arrangements for the thermocouple transmitter, thermostat and furnace and taking 0.5 to 1.5 g specimens. Calibration is effected by melting pure metals, the calibration curve then automatically compensating for systematic errors. 5) An inert atmosphere quenching installation (maximum specimen temperature 1400°C). 6) Vertical inert-atmosphere dilatometer and differential dilatometer for temperatures up to 1500°C. There are 10 figures.

SOURCE: AN UkrSSR. Institut metallofiziki. Sborník nauchny\*kh rabot, no. 18, 1964. Voprosy\* fiziki metallov i metallovedeniya (Problems in the physics of metals and physical metallurgy), 170-174

TOPIC TAGS: chromium ruthenium system, chromium ruthenium alloy, alloy phase diagram, alloy composition, alloy solid solution

ABSTRACT: Chromium-ruthenium alloys containing from 2.0 to 58.1 at% Ru were prepared by melting electrolytic 99.9% pure Cr and a powder of 99.86% pure metallic Ru in a nonconsumable electrode-arc furnace in an argon atmosphere. The alloys were annealed at 1500C for 25 hr, 1300C for 130 hr in argon, or at 900C for 150 hr and 800C for 100 hr in a vacuum, and water quenched. The phase diagram of the Cr-Ru system (see Fig. 1 of the Enclosure) was plotted on the basis of the differential thermal analysis. The  $\alpha$  +  $\beta$  eutectic, where  $\alpha$  and  $\beta$  are the solid solutions of Ru in Cr and of Cr in Ru, respectively, is

Card 1/3

ACCESSION NR: AT4042839

formed at 1610  $\pm$ 10C and contains 37.5 at% Ru. An intermetallic compound RuCr<sub>2</sub> ( $\sigma$ -phase) formed with a peritectoid  $\alpha$  +  $\beta$  reaction at about 1580C, has a homogeneity range of -2 at% Ru (from 35.5 to 37.5 at% Ru). The solubility of Ru in Cr varies from 34 at% at 1600C to 19 at% at 800C. The solubility of Cr in Ru varies from 52.5 at% at 1600C to 46 at% at 900C. Alloys with 20.2 to 31.4 at% Ru annealed at 800 and 900C contain a RuCr<sub>3</sub> compound (cubic lattice of the  $\beta$ -W type) and a RuCr<sub>4</sub> compound, the latter probably formed from the supercooled  $\alpha$ -phase containing 18—20 at% Ru. With the decomposition of the RuCr<sub>3</sub> compound at 780C into a mixture of the  $\alpha$ -phase increases from 1519 Mn/m² for pure Cr to 8820 Mn/m² for the maximum saturated solid solution. The  $\alpha$ -phase has a hardness of 10,388 Mn/m², and the maximum saturated  $\beta$ -phase has a hardness of 2040 Mn/m². Orig. art. has: 5 figures and 1 table.

TITLE: Niobium-cobalt phase diagram

SOURCE: AN UkrSSR. Institut metallofiziki. Sbornik nauchny\*kh rabot, no. 18, 1964. Voprosy\* fiziki metallov i metallovedeniya (Problems in the physics of metals and physical metallurgy), 175-177

TOPIC TAGS: niobium cobalt system, niobium cobalt phase diagram

ABSTRACT: Thirty niobium-cobalt alloys containing from 14.4 to 99.2 at 7 Nb were prepared by melting electrolytic cobalt and 99.4% pure niobium in a nonconsumable tungsten electrode-arc furnace in an argon atmosphere. The alloys were annealed in either argon or in vacuum at a temperature ranging from 1300 to 700C for periods várying from 50 to 435 hours. The phase composition was determined by metallographic and x-ray structural analyses, and a phase diagram of the Nb-Co system, based on data from the differential thermal analysis, was plotted (see Fig. 1 of the Enclosure). The intermetallic compound NbCo3 of the α + NbCo3 eutectic at 700—1000C is homogeneous at an Nb concentration of 28 to 33 at% and has a melting cord 1/3

ACCESSION NR: AT4042840

temperature of 1540  $\pm$ 10C. The alloys annealed at 700, 1000, or 1100C had only the  $\alpha$  and NbCo<sub>2</sub> phases. The intermetallic compound  $\beta$  is formed during crystallization at 1440  $\pm$ 10C and decomposed with the eutectoid reaction  $\beta \neq$  NbCo<sub>2</sub>+ NbCo at 1225  $\pm$ 20C. Decomposition of the  $\beta$ -phase at 1200C and its formation from the NbCo<sub>2</sub> + NbCo mixture can be achieved with 50-hr annealing. The NbCo intermetallic compound is homogeneous in the 700—1250C range at a Nb content of 45 to 54 at%. The solubility of Co in Nb, determined at 1250C, was about 1.57 at% (1 wt%). Two-phase (NbCo +  $\gamma$ ) alloys contained no other phases. Orig. art. has: 2 figures and 1 table.

Nb-Cr-Al alloys containing more than 50% intermetallic compounds in the structure also increases appreciably. The oxidation rate of unalloyed Nb and Cr was 83 and 0.59 mg/cm²·hr, respectively. Chromium additions (up to 8—10%) decrease the oxidation rate of Nb-Cr alloys more sharply than do subsequent additions. The oxidation rate in these alloys decreases until NbCr₂ starts forming. Fig. 1 of the Enclosure shows the effect of Al on the oxidation rate of Nb-Cr alloys. The oxidation rate of an Nb-Al₃ compound (0.84 mg/cm²·hr) is comparable to that of Cr. Alloys of the NbCr₂-NbAl₃ section have good oxidation resistance. Thus the Nb-Cr-Al system has several Nb-base alloys whose oxidation rate is below that of adjacent alloys containing more or less Al but with the same Cr content. Alloys containing 5—6 wt% Al or 4—7 wt% Cr have their lowest (5 mg/cm²·hr) oxidation rate at 1100C, i.e., 16 times below that of an unalloyed Nb. These alloys have a hardness of 400—470 and 290—350 kg/mm² at 20 and 900C, respectively. Orig. art. has: 3 figures and 1 table.

TITLE: Phase diagram of the Hf-Ta system in the solid state

SOURCE: AN UkrSSR. Institut metallofiziki. Sbornik nauchnykh trudov, no. 19, 1964. Voprosy fiziki metallov i metallovedeniya (Problems in the physics of metals and physical metallurgy), 206-211

TOPIC TAGS: hafnium, tantalum, hafnium tantalum system, hafnium alloy, alloy microstructure, alloy hardness/tantalum containing alloy composition

ABSTRACT: Sixteen binary Hf-Ta alloys, containing from 2.5 to 95 wt% Ta, arc melted in a tungsten electrode furnace in an argon atmosphere were investigated. Thermal analysis revealed no signs of melting at temperatures up to 1800C. However, an endothermal solid-state transformation was observed at 1000—1050C. A superaturated  $\beta_2$ -phase (a solid solution of Ta in Hf), stable at room temperature, was obtained by quenching alloy powders from 1300 and 1500C. The solubility of Hf in Ta was found to be 6,  $\frac{1}{8.8}$ , 16, and 33 wt% at 900, 1100, 1300, and 1500C, respectively. The x-ray diffraction patterns of Ta and an alloy with 80% Ta showed only the  $\beta_2$ -

Card 1/3>

L 39919-65

ACCESSION NR: AT5005125

phase lines (see Fig. 1 of the Enclosure). The diffraction pattern of Hf showed only the α-phase lines. However, the patterns of all alloys with up to 70% Ta contained no a-phase lines but those of a'-phase, a supersaturated solid solution of Ta in α-Hf. The maximum solubility of Ta in α-Hf was about 5 wt%. Alloys containing 10—20% Ta quenched from 1100, 1300, 1500, and 1700C contained an  $\omega$ -phase. The hardness of  $\alpha + \beta_2$  alloys annealed at 900C changes linearly, but with annealing at 1100C, it sharply rises at the Ta concentrations at which the solid w-phase is formed. Orig. art. has: 5 figures and 1 table.

reaction, chromium alloy, osmium alloy

ABSTRACT: Alloys of Cr and Os were made in an arc furnace with a Cu, water-cooled

ABSTRACT: Alloys of Cr and Os were made in an arc turnace with a Cu, water contained then subjected to homogenizing annealing at 1700C for 55 hrs. The phase equilibria diagram shown in Figure 1 of the Enclosure is of the eutectic type. The temperature of the eutectic reaction ( $L \rightleftharpoons A+A$ ) is  $1840 \pm 10C$ . The eutectic alloy contains 33 at. %(64 wt.%) Os. The  $\sigma$ -phase(Cr<sub>2</sub>Os) forms after crystallization of the eutectic in accordance with the peritectoid reaction  $A+A \rightarrow \sigma$  at  $1670 \pm 15C$ . Upon further cooling of the alloys, there is a further decomposition of the  $\sigma$ -phase in accordance with the eutectoid reaction  $A+A \rightarrow \sigma$  at 1670C, the  $\sigma$ -phase forms and decomposes under conditions of continuous heating and cooling. The compound Cr<sub>3</sub>Os is obtained in accordance

1.

with the peritectoid reaction  $\dot{\alpha} + \sigma \rightarrow Cr_3Os$  after prolonged annealing at 1540  $\pm$  40C. Hence, cast alloys of  $Cr_3Os$  consist of a solid solution of Os in chromium (d-phase). This same alloy, annealed at 1700C, has the structure  $\dot{\alpha} + \dot{\alpha}$ , and after annealing at 1500C and below,  $Cr_3Os$  forms. The  $Cr_3Os$  has a certain region of homogeneity. An increase in Os from 0 to 25 at.% increases microscopic hardness (from 150 to 600 kg/mm²) and the crystal lattice (from 2885 Å to 2930 Å) of chromium.  $Cr_3Os$  has a hardness of 600 kg/mm², while the hardness of the  $\sigma$ -phase, depending on the composition, ranges from 1800 to 2000 kg/mm², and the hardness of the saturated  $\beta$ -phase is about 800 kg/mm². Orig. art. has: 3 figures and 1 table.

TITLE: Investigation of chromium-iron-molybdenum and chromium-iron-tungsten alloys

SOURCE: AN UkrSSR. Institut metallofiziki. Sbornik nauchnykh trudov, no. 20, 1964. Voprosy fiziki metallov i metallovedeniya (Problems in the physics of metals and physical metallurgy), 108-124

TOPIC TAGS: chromium alloy, iron containing alloy, molybdenum containing alloy, tungsten containing alloy, alloy structure alloy hot hardness, alloy exidation fesistance

ABSTRACT: The following alloys have been investigated to determine which ternary Cr-Fe-Mo or Cr-Fe-W alloy would provide the optimum combination of the heat resistance of Mo or W and the ductility of Cr: binary chromium-iron alloys containing 45-90% Cr, chromium-molybdenum alloys containing 10-30% M, and ternary alloys containing up to 55% Fe and Cord 1/3

L 41560-65 ACCESSION NR: AT5008875

up to 30% Mo or W. In Cr-Fe-Mo alloys containing 45-50% Cr, additions of up to 6% Mo do not improve hot hardness or oxidation resistance. Increasing Mo content leads to the formation of a brittle o-phase which has a very low oxidation resistance in air at 1100C and lowers the oxidation resistance of the ternary Cr-Fe-Mo alloys in direct proportion to its content in the alloys. In Cr-Fe-W alloys, the single phase σ-region extends to about 32% W, but it tapers off at about 1275C. At high temperature (1450C), the single-phase region of α-solid solution with a b.c.c. lattice increases substantially, so that all the investigated alloys, except for an alloy containing 45% Fe and 30% W, became single-phase alloys at a more or less high temperature. A single-phase structure and a satisfactory ductility is readily preserved in all but three of these alloys by oil quenching from 1450C. Tungsten additions increase somewhat the melting temperature of Cr-Fe alloys, e.g., 30% W increases the solidus temperature by 100 and 150C in alloys with 40 and 50% Fe, respectively. Tungsten also increases the hardness of Cr-Fe-W alloys at both room and high temperature and does not impair their oxidation resistance. Orig. art. has: 8 figures and 3 tables.

TITLE: The hafnium-chromium phase diagram

SOURCE: AN UkrSSR. Fazovyye prevrashcheniya v metallakh i splavakh (Phase transformations in metals and alloys). Kiev, Naukova dumka, 1965, 159-162

TOPIC TAGS: hafnium alloy, chromium alloy, alloy phase diagram

ABSTRACT: The Hf-Cr system was investigated by metallographic and x-ray phase analysis of Hf-Cr alloys prepared in an arc furnace and subjected to various annealing treatments. Differential thermal analysis was used to determine the temperatures of the start and end of fusion. The phase equilibrium diagram obtained is shown in Fig. 1. The eutectoid equilibrium  $\beta \rightleftharpoons \alpha + \gamma$  was observed in Hf-rich alloys at  $1300 \pm 10$ C. Metallographic analysis of alloys annealed at 1500, 1200, and 1000C showed that alloys containing from 70 to 99.9 at.% Cr consist of two phases, and those with 99.95 and 99.97 at.% Cr have a single-phase structure. Thus, the solubility of hafnium in chromium was found to be 0.05-0.1 at.%; it remains practically unchanged as the temperature is lowered. Metallographic analysis of specimens annealed at 1200 and 1000C established that the solubility of chromium in hafnium does not exceed 2 at.% at these temperatures. The temperature of the polymorphous transformation in the compound HfCr<sub>2</sub> was found to be 1325  $\pm$  20C. Orig. art. has: 1 figure and 1 table.

Abstract

: Studies were conducted on 104 normal non-sensitized rabbits. When the carotid artery of 10 rabbits was infected with blood taken from a patient with rheumatism and processed with hyaluronidase, inflammatory changes appeared in the cardiac muscle more often than when other modes of administration were used. Upon introduction into the carotid artery of a hyaluronidase-treated extract from the valves and myocardium of a
